Delay of rooting (in storage) of potatoes by maleic hydrazide. E. Dunkels, E. Baumanis, and T. Smeltere. Latvian PSR Zinātnu Akad. Vēstis 1955, No. 7, 105-12 (in Russian; Latvian summary).—Potato plants were sprinkled with soln. of maleic hydrazide (I), with a detergent, at a rate of 1.5-2 kg. in 1000 l. H₂O per ha. one month before the collection of crop. Of the tubers collected 92-98% could be stored until the next season without developing sprouts, and were suitable for all purposes except seedling; I did not prevent budding of the sprouts, but arrested their further growth. The wt. and starch loss in storage was decreased by a factor of 2-3, vitamin C content was preserved, and metabolism during the storage was slowed down. A. D.

Title : A New Insulating Material and Its Use in Bee-Keeping.

Orig Pub : Vcelarstvi, 1956, 9, No 11, 166

Abstract : A newly produced insulating material, polystyrene, contains 97 percent of air and three percent foam (by volume). Due to its lightness ($1 \text{ m}^3 = 30-35 \text{ kg}$) and low heat conductivity (0.027), this material is suitable for the preparation of walls, bottom and other parts of the hive. It can be prepared with ease with the usual carpentry tools.

HNEVSOVA, V., SMELY, V., ERNEST, I.

hydrogenated at 50° with PtO_2 in C_6H_6 , yielding 2.03 g. *di-Me hexatetracontane-22,25-dione-1,46-diolate* (IX), m. 107.5-108° (from $\text{MeOH}-\text{C}_6\text{H}_6$). IX (1.52 g.) was converted by treatment with 2.5 ml. (HSCl) and 1.5 ml. $\text{BF}_3 \cdot \text{Et}_2\text{O}$ to the corresponding *bis(ethylmercaptide)*, m. 63-77°. Desulfurization by boiling in $\text{CaH}_2\text{-MeOH}$ (1:1) which with Raney Ni W4 gave 883 mg. of a product m. 88-7° which on subsequent hydrogenation with PtO_2 yielded 766 mg. *di-Me hexatetracontane-1,46-diolate* (X), m. 100-112° (from $\text{CaH}_2\text{-MeOH}$). X was also obtained in 70-mg. yield by a shorter alternative synthesis including treatment of 300 mg. VIII with (HSCl) $_2$ and $\text{BF}_3 \cdot \text{Et}_2\text{O}$, subsequent desulfuration and hydrogenation. Alk. hydrolysis of 300 mg. X by boiling with 5% methanolic KOH gave 212 mg. free acid, m. 128.5-9.5°. Similarly, treatment of *Me hexatetracontane-1,46-diolate* (X) with CuO gave *di-Me hexatetracontane-1,46-diolate* (X) in a 23.5% yield, while *Me hexatetracontane-1,46-diolate* (X) was decomposed to *di-Me tetracontane-7,10-dione-1,14-diolate*, m. 94-9° in 22.2% yield. IV. Selective reduction of unsaturated 1,4-diketones. Ivan Ernest, *Ibid.* 887 5.—Desulfuration of the *bis(ethylmercaptide)* (I) of *di-Et dodecane-5,8-dione-1,12-dicarboxylate* (II) depends considerably on the activity of the used Raney Ni. I was prepared by dissolving 4.0 g. Ia and 20 mg. hydroquinone in 4 ml. (HSCl) $_2$ and dropping into the cooled soln. 4 ml. $\text{BF}_3 \cdot \text{Et}_2\text{O}$. After 36 hrs. the mixt. was shaken with CaH_2 and 10% soln. of K_2CO_3 and the CaH_2 was shaken, leaving 0.6 g. clear viscous liquid of I. Desulfuration of I by boiling 1.21 g. in 120 ml. abs. EtOH with 25 ml. suspension of Raney Ni W4 (cf. Pavlic, C-4, 40, 6763) gave 330 mg. *di-Et dodecane-1,12-dicarboxylate* (III), b.p. 135-0°, m. 27° as the sole product. Alk. hydrolysis of II gave the free acid (III), m. 125-0°. Analogous procedure with a catalyst

(over)

HNEISOVA, V., SMELY, V., ERNEST, I.

that has been deactivated by boiling 2 hrs. with Me_2CO gave a fraction which was identified as a mixt. of 58% II and 41% of the corresponding unsatd. ester, probably *di-Et dodec-6-ene-1,12-dicarboxylate* (IV), characterized by coulometric analysis and by hydrogenation, yielding II. When a 12-hr. inactivation was used, desulfuration of 0.5 g. I gave a 900-mg. fraction, $b.p.$ 135-45°, which on alk. hydrolysis yielded crystals, $m.$ 125-7°, probably of $\text{HO}_2\text{C}(\text{CH}_2)_6\text{CH}=\text{CHCO}(\text{CH}_2)_6\text{CO}_2\text{H}$, whereas a 6-hr. inactivated catalyst produced a fraction, $b.p.$ 133-7°, apparently of IV, identified by hydrogenation which gave II and after alk. hydrolysis yielded III. A parallel expt. from 4.7 g. I gave a 1.18-g. fraction, $b.p.$ 124-7°, which was chromatographed on Al_2O_3 yielding by alk. hydrolysis of the lignine eluate 40 mg. *cryst. dodec-6-ene-1,12-dicarboxylic acid*, $m.$ 107-9°, confirmed by coulometric analysis. Attempts were made at overcoming difficulties encountered in the prepn. of unsatd. dicarboxylic acids of the type $\text{RO}_2\text{C}(\text{CH}_2)_n\text{COCH}=\text{CHCO}(\text{CH}_2)_n\text{CO}_2\text{R}$ (V) by prep. addn. compds. of V with anthracene (VI), however, without success. The adduct of Ia and VI obtained by heating 5 hrs. *powd. mixt.* of 3.6 g. VI with 0.8 g. V ($n = 4$, $R = \text{Et}$) forms crystals, $m.$ 78-9° (from cyclohexane- C_6H_6), yielding on sapon. crystals, $m.$ 135-4° (from $\text{C}_6\text{H}_5\text{-AcOH}$). Similarly was prep. the adduct of *di-Me oct-4-ene-3,6-dione-1,8-dicarboxylate* with VI from 0.7 g. VI and 1.0 g. V ($n = 2$, $R = \text{Me}$), forming needles, $m.$ 136.5° (from C_6H_5), and yielding on sapon. crystals $m.$ 213-14° (decompn.) (from AcOH).

Ed.: Soroka, M. S.; Tech. Ed.: Rudenskiy, Ya. V.

PURPOSE: This book is designed as a manual for engineers, designers
and technicians engaged in machine building. It may also
be used by foundry engineers.

COVERAGE: The authors stress the importance of castings in machine
design. In this book they describe the elements of design
of ferrous and nonferrous castings. A few chapters are
devoted to various methods of casting such as investment
precision casting, pressure casting, centrifugal casting,

TITLE: A digital infrasonic phase-frequency meter. Class 21, No. 189485 [announced
by the Kharkov Higher Master Engineering Academy (Khar'kovskoye vyssheye komandno-
inzhenernoye uchilishche)]

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 24, 1966, 41-42

TOPIC TAGS: digital system, phase meter, frequency meter, logic element

ABSTRACT: This Author's Certificate introduces a digital infrasonic phase-frequency
meter with intermediate time-pulse conversion containing a standard generator with
output connected through controlled rectifiers to the inputs of addition and subtrac-
tion pulse counters, a shaping network and a registration unit. Measurement accuracy
is improved and speed is increased by using a frequency divider connected to the input
circuit of the subtraction counter in series with a controlled rectifier, together
with a control unit based on logical elements and a reversible counter. One of the
inputs of the control unit is connected to the shaping network, the other input is
connected to the subtraction counter and the outputs are connected to the controlled
rectifiers.

DEEP DRAWING ON DROP HAMMERS (USSR)

Saparovskiy, S. V., and Ye. P. Smelyakov. Kuznechno-shtampovoye
proizvodstvo, no. 4, Apr 1963, 25-27. S/182/63/000/004/004/004

The Kuybyshev Aviation Institute has developed a special hydraulic unit (see illustration) which makes it possible to use the "elastic die-rigid punch" method for deep drawing on drop hammers instead of presses. Elastic die 1 is placed into steel container 2, which is fastened to the drop hammer ram. For better elasticity and more uniform distribution of pressure exerted on the blank, the

Card 1/3

AID Nr. 979-5 29 May

DEEP DRAWING ON DROP HAMMERS [Cont'd]

S/182/63/000/004/004/004

top part of the container is filled with water and a rubber bag filled with granulated rubber is placed into the bottom part of the container. The top part

Card 2/3

AID Nr. 979-5 29 May

DEEP DRAWING ON DROP HAMMERS [Cont'd]

S/182/63/000/004/004/004

(with fluid) of the container is separated from the bottom part by a rubber diaphragm. Floating piston 8 placed within steel cylinder 3 carries studs 7, which pass through the cylinder lid 3, and carry holder 6, blank 13, and hold-down ring 12. Interchangeable punch 9 is fastened to lid 10. The required fluid pressure in cylinder 3 is maintained by means of spring valve 11 in distributor box 4. Accumulator 5 receives fluid from cylinder 3 during the deep-drawing process and returns it by means of compressed air. The deep-drawing process is completed by several strokes of the ram with the reduction obtained in a single draw controlled by the spring of valve 14. After completion of the deep-drawing process, accumulator 5 is filled with compressed air which, with valve 14 open, forces the fluid into cylinder 3 and moves the piston 8 upward, removing the drawn part from the punch. Interchangeable tools (punch 9, holder 6, and ring 12) are made from case-hardened carbon steel for the deep drawing of duralumin, carbon steel, and alloy steel sheet 3 mm thick and heavier, and from zinc, wood, or plastic for the deep drawing of thinner gages. Experiments with hard-to-form materials were performed with preheating of the holder, blank, and ring. The method makes it possible to obtain draw ratios 8 to 10% higher than those in conventional dies. [SS]

TITLE: Stretch forming of metal sheets with vibrations

SOURCE: Kuznechno-shtampovochnoye proizvodstvo, no. 4, 1966, 23-24

TOPIC TAGS: metal forming, sheet forming, stretch forming, vibration forming

ABSTRACT: The effect of vibration in stretch forming has been investigated in forming D16AM aluminum-alloy sheets (200 x 300 x 1 mm). Vibrations were applied either perpendicular to or in the direction of the stretching pressure. Perpendicular vibrations with a force of 110—355 kg, a frequency of 45—70 Hz, and an amplitude of 0.3—0.8 mm increased considerably the relative deformation at the same stretching pressure. The relative deformations achieved in the first four stretch forming steps were 7.0, 12.5, 15.5, and 17.0% without vibration and 11.0, 17.5, 15.5, and 26.0 with vibration. Vibration in the direction of stretching pressure at a frequency of 20—30 Hz and an amplitude of 0.09—0.22 mm had a similar effect. It increased the relative deformation in five steps from 7.5, 9.5, 12.0, 14.0, and 16.0% to 13.5, 16.0, 20.0, 24.0, and 27.0%. Thus, vibration increases the relative deformation and makes it possible to achieve the desired shape in fewer steps or to use a lower pressure to achieve the same relative deformation compared to

Card 1/2

L 26272-66

ACC NR: AP6012612

conventional stretch forming without vibration. Vibrations applied simultaneously in both directions reduce the stretching pressure by 30% and increase the relative deformation from 22.5 to 33.0%. Orig. art. has: 1 figure and 4 tables. [WW]

REF SOURCE: Tr. Kafedry proiz-va letatel'n. apparatov. Kuybyshevsk. aviats. in-t, vyp. 20, ch. 2, 1965, 3-18

TOPIC TAGS: stepped extrusion, extrusion ratio, metal extrusion, buckling, bending, cupping

ABSTRACT: The process of cupping of each stage can be divided into bending and extrusion of the blank prior to the moment of buckling of the flange; extrusion with folds on the flange; and straightening of folds and moderate extrusion. The extrusion force is highest at the first stage; it is 30—40% lower than in conventional extrusion. Experimental data show that stepped cupping permits the use of an extrusion ratio 20—25% lower than that for conventional stamping. Intermittent loading also reduces

TITLE: Determination of force required for sizing the flange in extrusion with folding

SOURCE: Ref. zh. Tekhnologiya mashinostroyeniya, Abs. 9V143

REF SOURCE: Tr. Kafedry proiz-va letatel'n. apparatov. Kuybyshevsk. aviats. in-t, vyp. 20, ch. 2, 1965, 41-54

TOPIC TAGS: metal drawing, metal extrusion, force determination, flange sizing, extrusion, folding, sizing

ABSTRACT: Calculation of the force required for sizing a flange is cited. As an initial condition it is assumed that all folds formed during production are cylindrical in shape. Monograms were plotted for facilitating the use of the results obtained. The monograms were verified experimentally by pulsed drawing with folding of sleeves 50 mm in diameter from D16AM. The tests have confirmed that the force for sizing the flange calculated from monograms insures a normal extrusion process. Orig. art. has: 6 figures and a bibliography of 5 reference items. S. TITLE: Absorption and fluorescence spectra of certain azomethine
derivatives of benzidine and its 2,2' and 3,3' dichlorosubstitutes

SOURCE: Optika i spektroskopiya, v. 17, no. 4, 1964, 558-564

TOPIC TAGS: absorption spectrum, fluorescence spectrum, benzidine

ABSTRACT: For comparison with similar tests on salicylal aniline and its derivatives (DAN SSSR v. 143, 1145, 1962; ZhFKh v. 37, 2432, 1963), the authors investigated the absorption spectra of the condensation products of aniline, ortho-, meta-chloranilines, benzidine, and its 2,2' and 2,2' dichloroderivatives with salicylic and 2-oxy-1-naphthoic aldehydes in dimethylformamide, and the fluorescence spectra of frozen solutions (77K) of these substances in the same solvent. The doubling of the salicylal aniline molecule causes

Card 1/3

L 12908-65

ACCESSION NR: AP4047177

a bathochromic shift of the absorption and fluorescence bands, evidencing appreciable conjugation between the two halves of the disalicylal benzidine molecule. Disalicylal benzidine and its 3,3'-dichloroderivative differ very little in their absorption spectra; their fluorescence spectra are also of like character, but the fluorescence intensity of the latter is much larger than that of the former. At the same time, the absorption and fluorescence bands of 2,2'-dichloroderivative of disalicylal benzidine are less intense, owing to the spatial difficulties in the grouping of the biphenyl, and are shifted towards the short-wave end of the spectrum compared with the disalicylal-benzidine and disalicylal-3,3'-dichlorobenzidine. The rules characteristic of the derivative of salicylic aldehyde hold true also for the absorption and fluorescence spectra of the products of condensation of the foregoing amines with 2-oxy-1-naphthaldehyde. Plots of the various spectra and of the time variation of the fluorescence intensity are presented. The azomethine derivatives of the diamines of the benzidine series are

SOURCE: Moscow. Inzhenerno-fizicheskiy institut. Inzhenerno-fizicheskiye voprosy yadernykh reaktorov (Problems of nuclear reactor engineering and physics); sbornik statey. Moscow, Atomizdat, 1966, 78-84

TOPIC TAGS: nuclear reactor, transport equation, breeder reactor

ABSTRACT: The critical dimensions of reactors of several different geometries are found using the general solution of the one-group transport kinetic equation in the breeder material. The Fourier integral expansion of the general solution is of the form

$$\varphi_1(q, \Omega) = \frac{A_1 c_1}{8\pi} \int_{-\infty}^{\infty} dx' e^{ix'q} \frac{\delta(x' - x_1) + \delta(x' + x_1)}{1 + ix'\Omega},$$

where $x_1 = \frac{x}{\Sigma_{fp}}$ is the dimensionless material parameter of the breeder material determined by the characteristic equation

$$\frac{x_1}{\text{arctg } x_1} = c_1; \quad c_1 = \frac{\nu_f \Sigma_f + \Sigma_a (1 - \bar{\nu})}{\Sigma_{tr}} > 1,$$

 4125. Relay protection of the booster transformers
 for longitudinal and voltage regulation. B. YA.
 SMELYANSKAYA and A. B. CROKOT. *Elektricheskoe*
 1954, No. 5, pp. 23. In Russian.

Booster transformers used nowadays for this purpose usually comprise a pair of magnetically separated transformers within one casing, the first transformer being the regulating autotransformer with tapings, supplied from the l.v. winding of the main transformer and the second (the "series" transformer) supplied from the autotransformer. The secondary winding of the series transformer is connected to the neutral terminals of the h.v. winding of the power transformer. Under certain conditions it is possible to combine the differential protections of power and regulating transformers, these conditions being analysed in the paper. It is not easy to prevent the protection from responding to the regulating currents and simultaneously keep it sensitive to internal s.c. currents in the regulating transformer. This is quite impossible with some of the circuit variants suggested and other variants presuppose the use of relays with damper windings. Similar difficulties are also met with in variants using saturable transformers for interconnection of the relays. Discrimination between internal and external short-circuits is required and this is made possible by "blocking" current relays inserted in the main transformer circuit. Problems of overcurrent protection are also considered. B. P. KRAUS

ABSTRACT: An engineer since 1929, A. B. Chernin has worked for years in developing new techniques and equipment for relay protection of electric power systems. In this 60th birthday tribute, he is credited with leading the group which produced the directives on relay protection, contributing to the development of a method for calculating transient processes in long distance 400-500 kv power transmission lines and with aiding in planning of the electric portions of power stations, substations and power systems. The results of his engineering and scientific work have been published 46 times, he is a doctor of technical sciences (since 1963), and has taught for 30 years at the Moscow Power Institute. TITLE: Concerning the nature of dielectric losses in glasses at microwave frequencies

SOURCE: Fizika tverdogo tela, v. 7, no. 4, 1965, 1008-1011

TOPIC TAGS: alkali free glass, dielectric loss, dielectric constant, solid dielectric, microwave loss

ABSTRACT: Apparatus is described for the measurement of the dielectric constant and the tangent of the dielectric loss angle of a solid dielectric at 3 cm wavelength in the temperature interval 100--300K. The measurements were made by a cavity method at a H_{01} load by determining the change in the Q and in the resonant length of the cavity upon introduction of the sample. The cavity was excited from a type 51I generator through a coupling aperture, and the indicator was a galvanometer. The linear dimensions of the cavity were varied with a micrometric screw and measured with a micrometer scale. Typical results are shown in Fig. 1 of the Enclosure, and indicate that the dielectric losses in alkali-free glasses have a

BUDNIKOV, P. P., SMELYANSKII, I. S., AND ENDOVITZKY, V. I.
Tests of refractory materials under pressure at high temperatures. Keram. i Staklo, 6 [4] 192-95 (1930).—A description of tests with refractory materials under a pressure of 1 kg./sq. cm. at high temperatures is given. The experiments were made in electric kilns of Steger and Hirsch-Hesht. Grog blocks began to deform at 1250 to 1350°.

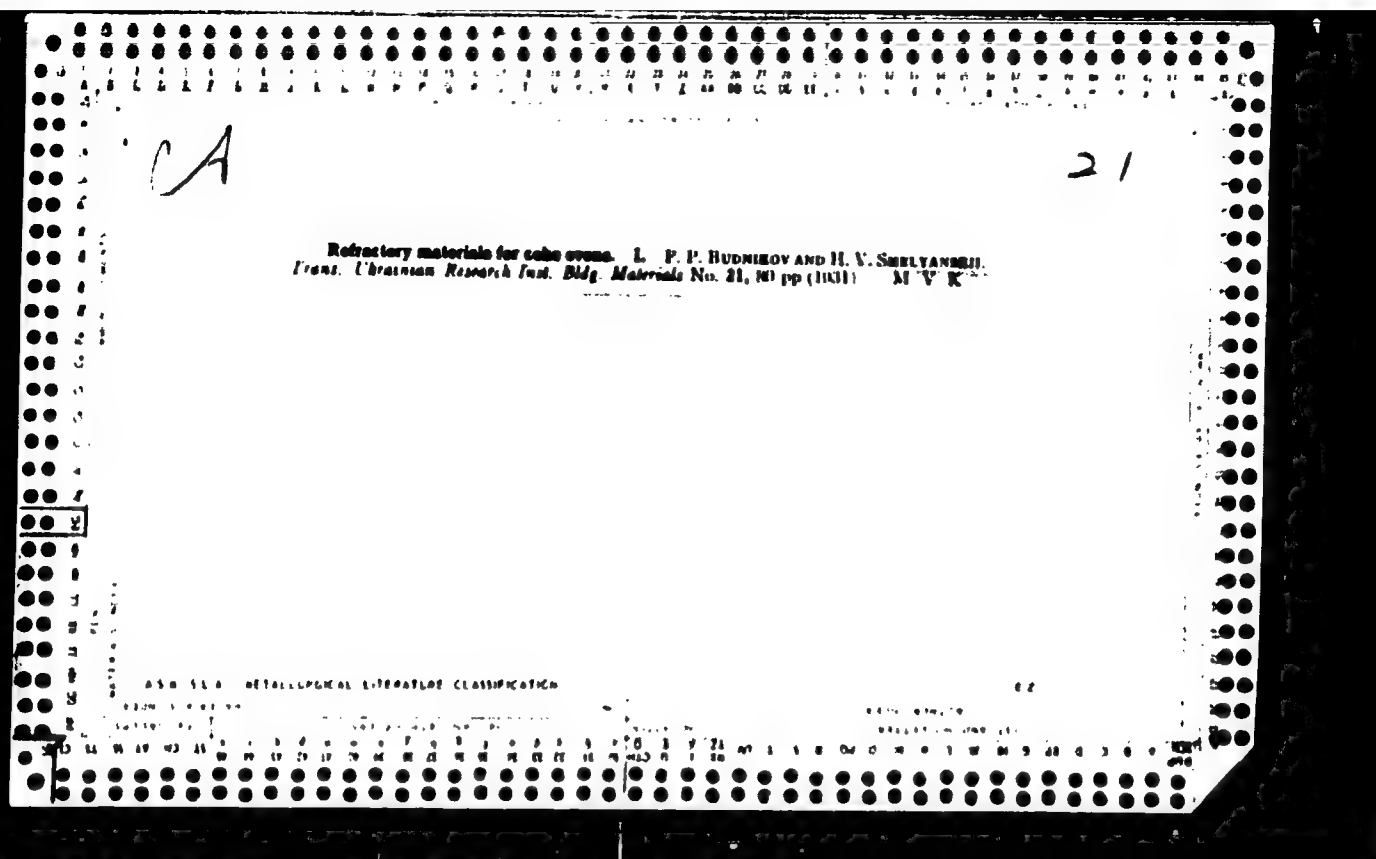

SMELYANSKIY, I. S.

The tridymitization of quartz in silica brick in the presence of mineralizers and by partial replacing of quartzites by sand in the batches, for silica brick making. I. I. Budnikov and V. S. Smelyanskiy. Trans. Ukrainian Sci. Research Inst. Silicate Ind. (U. S. S. R.) 15, 28(1931); J. Soc. Glass Tech. 17, 314-15A.---The Yasinovats-Avdeyevsky quartzites investigated have the following av. compn.: SiO_2 99.52%, Al_2O_3 1.65, Fe_2O_3 1.76, CaO 0.74, MgO traces, loss on ignition 0.39. The sp. gr. is 2.625 and m.p. 1730°. From 62 batches of these quartzites with different addns. silica bricks have been prepd. Conclusions: (1) The quartzites were of av. quality in comparison with pure cryst. and so-called amorphous quartzites. They were slowly transformed, so that to obtain 1st-grade silica bricks either the burning temp. should be high (1460-70°) maintained for 24-8 hrs., or the quartzites should be mixed with those easy of conversion. (2) of 3 mixts. with different granulometric compns. the most suitable had the following compn.: 10% grains from 5 to 2.5 mm., 40% grains from 2.5 to 1mm., and 50% from 1 mm. to dust. (3) the open-hearth slags undoubtedly promote the tridymitization of quartz and the obtaining of uniform, dense bricks with true and strong corners and edges (without holes and flaws). These properties are obtained by addn. of 1-3% of open-hearth slags. It is not recommended to introduce into the batch more than 3% of open-hearth slags, as increase above this does not correspondingly increase the tridymitization of quartz. (4) Phosphorites of Isyum are excellent mineralizers, promoting the transformation of quartz into tridymite and the obtaining of a uniform dense body. The optimum quantity of this addn. is 2-3% of the wt. of the dry substances of the batch. (5) Water glass is a more active mineralizer than open-hearth slags and phosphorites, but it gives a less dense body. The optimum quantity is 1%. (6) Mn oxides promote the conversion of quartz into tridymite. (7) Coal ashes of the av. compn. SiO_2 37.10-49.45, Al_2O_3 38.00--

| <p>Manufacture of first-grade silica brick for the steel industry from crystalline quartzites. I S SMIRLYANSKII AND A S FERNESI. <i>Trans Ukran. Sci. Research Inst. Silicate Ind</i> 10(1931); <i>Ceram. Abstracts</i> (in <i>J. Am. Ceram. Soc.</i>) 11, 436. The investigated quartzites have the following properties: compn., SiO_2 97.22, Al_2O_3 0.06, Fe_2O_3 0.78, CaO 0.80, MgO trace, ignition loss 0.26%, sp. gr. 2.65, refractonness Seger cone 34 (1750°). The expts. have been carried out on lab. and com. scales to study the influence of different addns. and conditions of manuf. on the rate of inversion of quartz in silica brick. The silica brick obtained were bested in an open-hearth furnace. Conclusions: (1) The investigated cryst. quartzites are slowly transformed during firing. They are suitable for the manuf. of first-grade silica brick if the batch is well mixed in an edge mill, carefully molded, and fired at Seger cone 16 for 24 hrs. (2) Though by a finer granular compn. the inversion of quartz is more intensive, the authors recommend the use of a grind of quartzites subjected to a control sieving through a sieve with openings of 6 mm. The contents of grains in size less than 0.5 mm. should be nearly 50%. By the use of such a grind silica bricks are obtained having a greater thermal strength and resistance against the action of dust and slag. (3) The introduction into the batch of more than 2% of lime is unnecessary, as it lowers the refractonness of silica brick without increasing the inversion of quartz. (4) Increasing the moisture of the batch improves the quality of the silica brick. The max. of moisture</p> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| <p>ASB-SLA METALLURGICAL LITERATURE CLASSIFICATION</p> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

(by hand molding) should be limited by the ability to retain the regularity of shape of the green brick. (5) The addn. of 25% of sand does not lower the quality of the silica brick. (6) The addn. of previously fired quartzites in the quantity of 20 to 50% increases, in some measure, the inversion of quartz. For the manuf. of brick not of intricate shapes or great size, however, such an addn. is unprofitable from the economic point of view and only complicates the process of manuf. (7) The blast furnace throat dust is a good mineralizer for the inversion of quartz into tridymite. By its introduction into the batch, if the other conditions remain const., well tridymitized silica brick are obtained. The optimum quantity of this addn. is 2%. One disadvantage of this mineralizer is that being a dust it need not be ground. Its disadvantage is its fluctuating chem. compn. depending on the phys. state of the material charged in the blast furnace and of the work of the furnace. (8) Well tridymitized silica brick are obtained with welding slags as mineralizers. The optimum quantity of this addn. is 2%. Their advantage is that nearly all of the Fe present is in the form of suboxide. The disadvantage is the necessity of fine grinding complicated by their high hardness. (9) The addn. of molasses does not influence the inversion of quartz, although its introduction in the quantity of 0.25% is desirable, as it considerably decreases the waste of green brick and aids in retaining true corners and edges of the brick. (10) The addn. of reducing agents such as coke and charcoal considerably promotes the inversion of quartz into tridymite; especially good results are obtained with charcoal. The introduction of these addns (when ferruginous mineralizers are used) is also necessary to increase the porosity of the silica brick, its thermal strength being influenced. The quantity of these addns. should be from 1.5 to 2.0%. An increase in their quantity increases the difficulty of molding. (11)

Synopsis: L. K. DYNAS FROM CRYSTALLINE QUARTZ.
 (U.S.S.R. Academy of Sciences, State Sci. Tech. Pub. House of Ukraine, Kharkov, and Kiev, 1961. 40 pp., 17 fig. Phys. Chem. Abstracts, 11 [8] 450 (1962)) and has been undertaken to prepare dynas from crystalline quartzites in plant scale and to test the product in open hearth furnaces. From the 22 batches the following were chosen:

| No. of batches | Quartzite A (%) | River sand (%) | Calc (%) | Molao-see (%) | Int. slag (%) | Char. coal (%) |
|----------------|-----------------|----------------|----------|---------------|---------------|----------------|
| 1 | 100 | 0 | 0 | 0.25 | 1.5 | 1.5 |
| 11 | 75 | 25 | 1.5 | 0.25 | 1.5 | 1.5 |
| 21 | 100 | 0 | 1.5 | 0.25 | 1.5 | 1.5 |

The chemical composition of the components is as follows:

| | Quartzite A (%) | River sand (%) | Int. slag (%) |
|--------------------------------|-----------------|----------------|---------------|
| Fe | | | 11.04 |
| Na ₂ O | 07.10 | 07.8 | 11.10 |
| Al ₂ O ₃ | 0.70 | 0.52 | 1.41 |
| Fe ₂ O ₃ | 0.70 | 0.62 | |
| CaO | 0.78 | 0.61 | 1.51 |
| P ₂ O ₅ | | | 0.12 |
| MgO | 0.06 | | 0.1 |
| MnO | | | 0.07 |

Ignition loss 0.11
 P.C.C. Seger cone 31 (1750°C)

The granulometric composition is as follows:

| Quartzite grains | (%) |
|------------------|-----|
| From 7.5 mm | 1 |
| " 5.3 mm | 17 |
| " 3.1 mm | 25 |
| " 1.05 mm | 11 |
| Less than 0.5 mm | 41 |

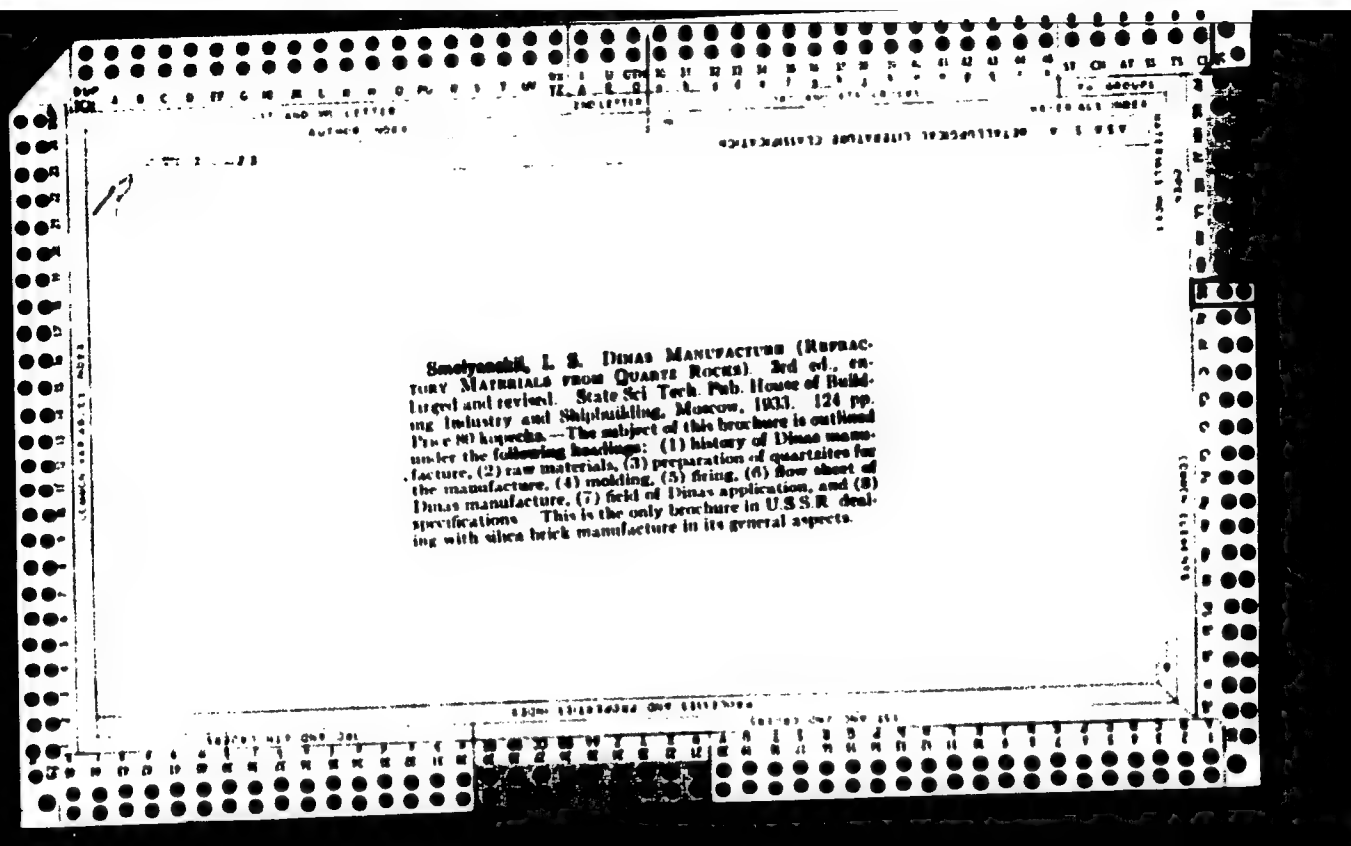

Int. slag through a sieve (100 mesh cm²)
 Charcoal through a sieve with apertures 1 mm
 Sand through a sieve with apertures 1 mm.
 Moisture of the mixture moistened with lime milk is 8.5% of the weight of the dry powder.
 The highest temperature of firing was Seger cone 16 (1400°C).

On the basis of testing the silica brick for the laboratory and service life in crowns and heads of 25, 50, 100 ton open-hearth furnaces, the following conclusions were drawn: (1) The investigated crystalline quartzites are slowly transformed during firing. They are suitable for the manufacture of first grade silica brick. If the conditions of manufacture are properly chosen, i.e., by a correct granulometric composition of the batch, good treatment of the mass in a wet edge mill, careful mulling, and proper firing, only high-grade silica brick are obtained from these quartzites with the usual addition of 2% lime. (2) The optimum granulometric composition of the mass should be as follows:

| Grains from | (%) |
|-------------|-------|
| 5.3 mm | 6.8 |
| 4.1 mm | 20.25 |
| 1.15 mm | 15.20 |
| 0.5 mm | 40-45 |

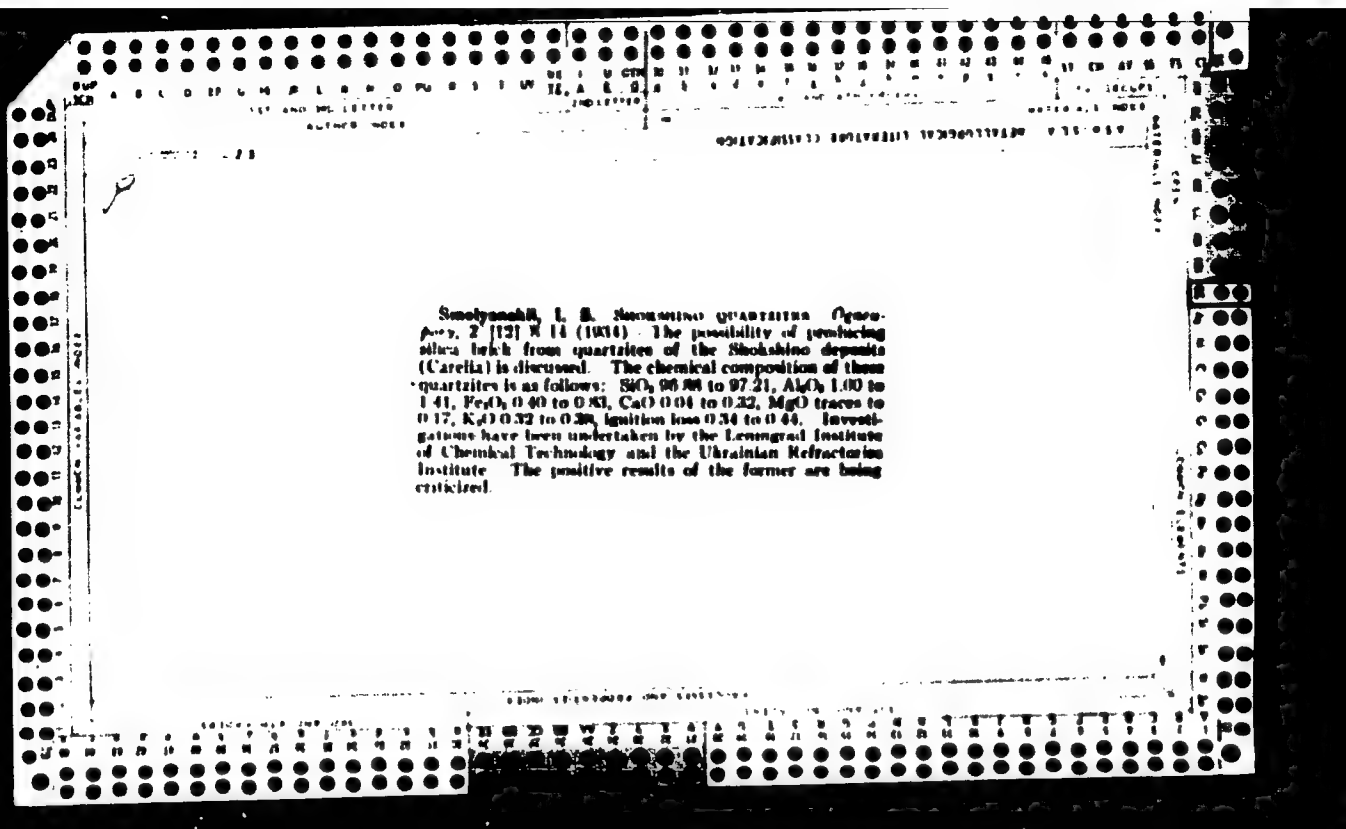

To increase the per cent of yield by firing silica brick with cast flaws and cracks it is necessary to prevent the introduction into the mass of grains greater than 5 mm. It is necessary to introduce into the batch 15 to 25% of broken silica brick when Dinas of great size is manufactured. Special attention should be given to the great quality of lime. Lime milk should not contain particles of undissolved lime. There should be about 2 to 2.5% of free lime in the mass. The green brick when introduced into the furnace should not contain more than 1% moisture. (3) The addition of 0.25 to 0.125% molasses increases the mechanical strength of the green brick and lowers the waste. (4) The introduction in the Dinas batch of 25% quartz sand considerably eases the molding of the Dinas green brick and does not lower the quality of Dinas. (5) An increased moisture of the mass improves the quality of Dinas considerably. The amount of moisture is limited by the possibility of the green brick losing their regular shape. (6) Pit slags ("welding" slags) are undoubtedly excellent mineralizers, promoting a more definite crystallization in Dinas of lanceolate forms of trisilicate, they should be finely ground and carefully mixed with the quartzite powder.

per. If the last indication is not taken into consideration the slags promote the formation of pores (bubbles) with a lowered melting temperature. The optimum quantity of this addition is 1.5 to 2%. With the addition of pit slags there should be introduced into the batch about 1.5% coke dust or, still better, the same quantity of powdered charcoal as a reducing agent and to increase the porosity and thermal strength of Dinas. Dinas which contains 1.5% pit slags and 1.5% charcoal, i.e. the so-called black Dinas (often called brown Dinas), has a higher thermal strength than the ordinary white Dinas in firing and ending time (during manufacture) and in its service in open-hearth furnaces. The disadvantage of black Dinas at the temperatures in open hearth furnaces is its somewhat decreased refractoriness. (7) For firing high grade Dinas from the investigated crystalline quartzites it is necessary to bring the firing temperature to Seger cone 16 and maintain this temperature about 16 hr. There is no necessity of raising the firing temperature higher than Seger cone 16 and this is not recommended because of the danger of formation of sharp flame and increase in yield of Dinas with flaws. (8) (a) Dinas made from batch No. 1 is somewhat more stable than the ordinary Dinas from amorphous quartzites; (b) Dinas from batch No. 21, used in the crowns of open-hearth furnaces, is nearly as stable as Dinas of batch No. 1 and plant Dinas from amorphous quartzites, but in the heads of open hearth furnaces it is somewhat less stable because of its decreased refractoriness; (c) Dinas from batch No. 13 used in crowns of open-hearth

Smelyanskii, I. S., and Drushnikova, L. V. GRANULOMETRIC COMPOSITION OF SILICA MASSES. *Ogneyerny*, 2 [10] 13-18 (1934).—Several authors demonstrated that the physical properties of silica brick depend largely on the granulometric composition of the mass, a higher density of the brick being obtained by an appropriate proportion between the different fractions. Experiments based on experimental selection of an optimal filling up of a given volume with grains of different dimensions were undertaken by the authors. Nine fractions from 0 to 6 mm. were prepared; material of different granulometric compositions was poured into a cylinder and shaken down to fill a volume of 250 cu. cm., and the volume weight was calculated, based on the volume porosity. The results obtained demonstrated that masses of highest density and volume weight may be obtained when all fractions are used in appropriate proportions. Removal of the coarser fractions resulted in changes for the worse. The form of grains does not influence the density of the mass, but the use of grains of an angular form, owing to their advantage in the physicochemical processes during the firing process, is recommended. The best results were obtained with compositions calculated on the basis of the Litzow curve for grog materials; the volume weight obtained was 1.96 to 1.99.

Sulfite-cellulose lye instead of melasse. I. S. Smel-
yanetskiy. Opat'skaya 8, 100-2(1935).—Quite satisfactory
results were obtained with lye used even in addn. to 2%
of lime in a proportion of 0.125-0.26%; the strength of
brick pressed on Buchan pressure before burning increased.
The mineralogical structure of the brick is in no way
influenced.

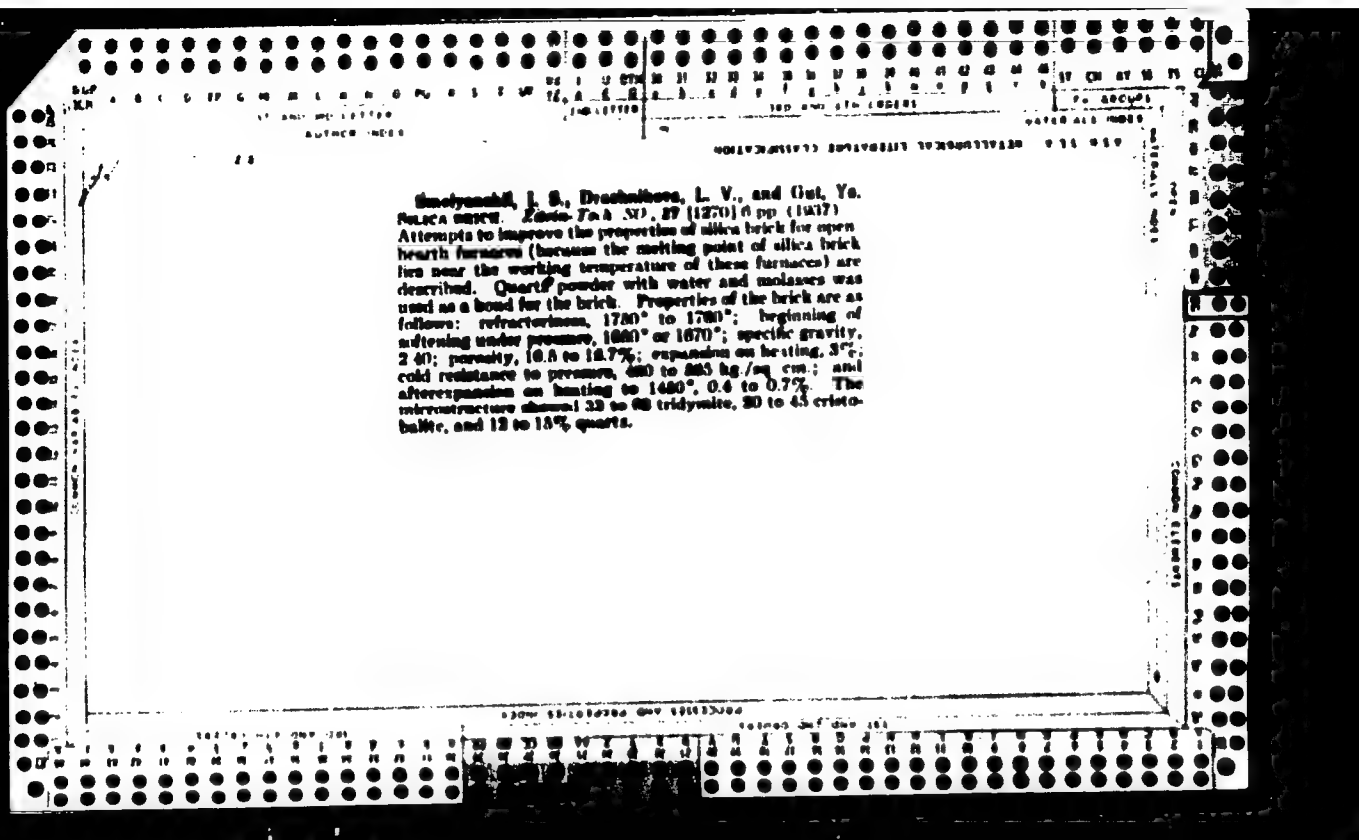

E. H. Stefanowich

Smolyanskii, I. S., Drashkova, L. V., and Lomitschenskii, S. *Russkaya Zashchita*, 50, 27 (1933) 4 pp. (1936); reviewed in *Referat Silikatov*, 5, 3478 (1936). The new silica brick withstands 43 charges in the crown of an electric steel furnace. The resistance to firing of silica brick is affected by the properties of the raw materials and the amount of lime added. The fusing point of pure quartzite is 1780°, and that of a silica brick with 2% lime is 1720° to 1730°C. Obviously, a low lime addition is desirable. Tests show, however, that (under similar conditions) the brick with less than 2% lime had a dull ring and cracks because the thickness of the lime film was inadequate. To obtain a sufficiently thick lime film with less than 2% lime, the total surface of the grains in the mix was lowered by using coarser grains (corrections for granulometric curves are given). In the new silica brick, the moisture content is 5.6 to 6.3% (old brick 6 to 6.8%); the lime content is 1.5%, and much better properties are obtained.

Smelyanskii, I. S. MANUFACTURE OF DINAS BRICK WITH INCREASED RESISTIVITY. *Sov. S* [4] 76-78 (1938). — One of the principal methods of increasing the thermal resistivity consists in preparing Dinas brick from a mass with a large granulated composition and a reduced content of lime. Brick prepared from such a mass, called electro-dinas, were not destroyed by firing tests. The mass of electro-dinas contains grains of quartzite of 8 mm. and about 30 to 35% of grains of 0.5 mm. Because of the presence in ordinary Dinas brick of 50 to 60% of small grains and about 3% of lime and other oxides, about 10% of glass is formed in firing which shows poor heat resistivity of these brick. Electro-dinas contains about 1.6% of lime and a maximum of 35.8% of grains up to 0.5 mm. The composition of electro-dinas is quartz 18, cristobalite 17, tridymite 66, and glass about 8.8%. S. describes the results of tests of electro-dinas brick in the roof of an electrical furnace of the Elektrostal works. During the fusion, boiling, and reheating of metals, visible fissures and breakage of the brick were not evident. Electro-dinas brick in the roof of an 8-ton electrical furnace withstood 43 fusions. The minimum mechanical strength of electro-dinas is double that of ordinary Dinas brick, and electro-dinas possesses a higher heat resistivity. To raise the refractoriness of Dinas to 1750°C., S. prepared a Dinas brick with a siliceous binding and without lime.

Smelyanskii, I. S. SILICA BRICK WITH A SILICOUS BOND. *Thesis, Nauch.-Issledovatel. Inst. Ogneperv. & Kislodoprov., No. 44, pp. 20-43 (1938).*—A method for manufacturing silica brick with a siliceous bond (without lime) having the same refractoriness as quartzites has been suggested. Due to a replacement of the lime bond by a siliceous bond, the chemical composition of these brick does not differ from the average composition of quartzites from which the brick is produced. Hence the refractoriness of such brick depends basically on the refractoriness of the raw materials. Silica brick with a refractoriness of 1770°C. may be obtained when using quartzites with a high silica content free from fluxes (mica, etc.). The advantage of such silica brick over silica brick with a lime bond is that the former have a higher silica content and therefore have a higher refractoriness. Various types of quartz containing 90 to 97% silica may be used as raw materials for the siliceous bond. The most suitable are crystalline quartzite or cement quartzite with a retarded velocity of transformation.

Smolyanitskii, I. S., and Tolstov, V. D. Effect of composition, charging, and conditions of firing on the strength of silicon nitride. *Journal of Materials Science*, 7 (6) 382-87 (1969). —Data characterizing the effect of charging, conditions of firing, and additions to the mix of crystalline quartzite on silica brick are given. Firing in a reducing or neutral atmosphere improves the qualitative values of silica brick.

786. THE INFLUENCE OF CRYSTALLINE QUARTZITES AND THE FIRING SCHEDULE ON THE STABILITY OF COKE-OVEN SILICA REFRACTORIES IN FIRING.—I. S. Smolyanski, V. D. Tuglov and A. N. Miroshnik (Ogarev, 7, 104, 1988). Manufacturing losses at a Russian silica brickworks ranged from 8 to 25%. The causes were traced to breakage and surface contamination. Production methods were developed to overcome this high wastage.

| <p>COKE OVEN DINAS WITH MANGANESE BINDER. I. S. Smal- yanekii and V. D. Teigler. <i>Doklady Akad. Nauk SSSR</i>, 14 [1] 9-21 (1949). -- High-quality Dinas suitable for coke ovens was prepared from a mixture of 85% Ovruch quartzites and 15% Dinas scrap containing 39% < 0.088 mm., using a CaO binder. The addition of this charge of 0.5% (based on Fe₂O₃) ferruginous mineralizers improved the porosity, reheat growth, temperature of deformation under load, wear resistance, and heat conductivity. Transformation of quartz was not affected to a marked extent, but the forma- tion of hematite crystals reduced the resistance to carbon- containing gases; hence, the addition of large amounts of ferruginous substances to increase tridymitization is not recommended. Dinas prepared from the above charge but using an Mn binder (1 MnO + 1% CaO) compared favorably with Dinas made with iron binder. Characteristics were as follows; specific gravity 2.373 and 2.372, compres- sive strength 356 and 337 kg./cm.², porosity 20.0 and</p> | | | | | |

| SOURCE | | SUBJECT | | CLASSIFICATION | |
| 1 | | 2 | | 3 | |

20.2%, refractoriness 1710 and 1710°C., temperature of deformation under load of 2 kg./cm.² 1656 and 1654°C., reheat growth 0.28 and 0.75%, heat conductivity 1.70 and 1.50 cal./hr.m.²°C., wear resistance 0.28 and 0.47 gm./cm.², tridymite content 69.3 and 62.5%, cristobalite content 19.0 and 23.5%, and quartz content 11.6 and 14.0% for Dinas with Mn and iron binder, respectively. A still greater degree of tridymitization was obtained from the same charge having 42% < 0.088 mm. and a maximum grain size not over 3 mm. The properties of Dinas with Mn binder were not impaired by using a charge consisting of 60% Ovruch quartzites, 25% Prechistov quartzites, and 15% Dinas scrap. Most effective ratios of MnO:CaO vary from 1:1 to 1:2; the first ratio is preferred, and absolute amounts should be 1% MnO and 1% CaO. Nikopol Mn ores can be used as the binder. For best results, charges containing 50% or more of Ovruch quartzites should have the following granulometric composition: maximum grain size 3 mm., 15 to 20% 0.5 to 0.088 mm., and about 40% < 0.088 mm.

Apparatus for determining the thermal stability of silicon brick for coke ovens. I. S. KALINABEKI AND I. S. SMELYANSKII. *Zashchita Lab*, 15 [7] 873-76 (1949). The apparatus consists of a brick oven in which the front and side walls are the test brick. The furnace is heated with two Silit rods; after 3 to 4 hr, the temperature inside the front wall is not less than 1200°C and that on the outside up to 650°. The front wall is then subjected to rapid cooling to 70° or 300° with a water spray. After three heat shock cycles, the front wall brick were subjected to an abrasion test with quartz sand. Thermal stability was evaluated on the basis of resistance to abrasion. Loss in weight of brick cooled to 70° was greater than for those cooled to 300°. The brick were taken from partition walls near the top of the vertical flues, but brick from the bottom of the oven can also be used for this evaluation. 3 photographs. B.Z.K.
